

## Experiment - 6

**AIM-** To implement distance vector routing algorithm.

**Description** - A distance-vector routing (DVR) protocol requires that a router inform its neighbors of topology changes periodically. Historically known as the old ARPANET routing algorithm (or known as Bellman-Ford algorithm).

### Algorithms:

1. A router transmits its distance vector to each of its neighbors in a routing packet.
2. Each router receives and saves the most recently received distance vector from each of its neighbors.
3. A router recalculates its distance vector when:
  - a) It receives a distance vector from a neighbor containing different information than before.
  - b) It discovers that a link to a neighbor has gone down.

**The DV calculation is based on minimizing the cost to each destination**

$D_x(y)$  = Estimate of least cost from x to y

$C(x,v)$  = Node x knows cost to each neighbor v

$D_x = [D_x(y): y \in N]$  = Node x maintains distance vector

Node x also maintains its neighbors' distance vectors

- For each neighbor v, x maintains  $D_v = [D_v(y): y \in N]$

### Code:

```
#include<bits/stdc++.h>
```

```
using namespace std;
```

```
int main(){
```

```
    int n;
```

```
    cout<<"Enter the number of nodes in the network: ";
```

```
    cin>>n;
```

```
    vector<vector<int>> distTable(n+1, vector<int> (n+1, 10000));
```

```
    for(int i=1; i<=n; i++){
```

```
        int childs;
```

```
        cout<<endl;
```

```

    cout<<"Enter the number of nodes connected to node "<<i<<": ";
    cin >> child;
    distTable[i][i] = 0;
    if(child>0){
        cout<<"Enter nodes and their distances: "<<endl;
    }
    for(int j = 0; j < child; ++j){
        int sibling;
        int distance;
        cin >> sibling >> distance;
        distTable[i][sibling] = distance;
        distTable[sibling][i] = distance;
    }
}

bool done = false;
while(!done){
    done = true;
    for(int i=1; i<=n; i++) {
        for(int j=1; j<=n ; j++){
            for(int k=1; k<=n; k++){
                if(distTable[i][j] > (distTable[i][k]+distTable[k][j])){
                    distTable[i][j] = distTable[i][k] + distTable[k][j];
                    done = false;
                }
            }
        }
    }
}

cout<<endl;
cout<<"Distance Matrix: "<<endl;
for(int i=1; i<=n ; i++){
    for (int j=1; j<=n ; j++){
        if(distTable[i][j] == 10000)
            distTable[i][j] = -1;
        cout<<distTable[i][j]<<" ";
    }
    cout<<endl;
}

return 0;
}

```

## Output:

```
File Edit View Search Terminal Help
prince@pp-asus:~/lab/CN/6.distanceVector$ g++ distanceVector.cpp
prince@pp-asus:~/lab/CN/6.distanceVector$ ./a.out
Enter the number of nodes in the network: 4

Enter the number of nodes connected to node 1: 2
Enter nodes and their distances:
2 5
4 1

Enter the number of nodes connected to node 2: 2
Enter nodes and their distances:

## Learnings -

1. **Advantages of Distance Vector routing -**
  - It is simpler to configure and maintain than link state routing.
2. **Disadvantages of Distance Vector routing -**
  - It is slower to converge than link state.
  - It is at risk from the count-to-infinity problem.
